

Planetary Atmospheres - Molecular Spectroscopy

Olivia Venot
olivia.venot@lisa.ipsl.fr

ARES 2, Biarritz, October, 5th 2021

Outline

- Introduction
- Energy levels, structure of molecules
- Electronic, vibrational, rotational transitions
- Collision-Induced Absorption
- Molecular and Planetary spectra

Spectroscopy

Wakeford et al. 2017

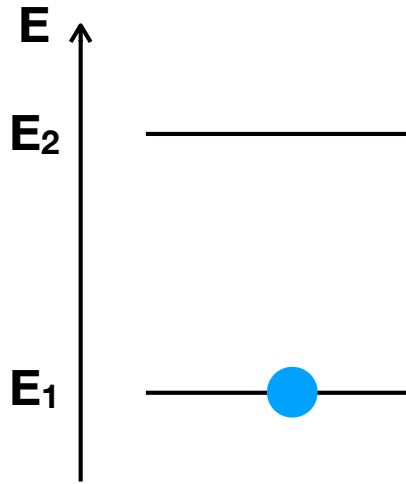

FIG. 6.— The complete transmission spectrum of WASP-39b (black points). This transmission spectrum incorporates data from HST STIS and WFC3, *Spitzer* IRAC, and VLT FORS2 completing the spectrum from 0.3–5.0 μm with currently available instruments. Using the ATMO retrieval code, which implements an isothermal profile and equilibrium chemistry, we determine the best fit atmospheric model (red) and show the 1, 2, and 3 σ confidence regions (dark to light blue) based on the retrieved parameters.

Why are we able to say that H₂O, CO₂,... are in the atmosphere ?

➡ thanks to molecular spectroscopy !

Spectroscopy

- Molecules have discrete energy states

- E₁, the lowest energy level, is called ground state

Spectroscopy

- Molecules have discrete energy states

- An electromagnetic wave (a photon) induces transition between energy levels of a molecule

Spectroscopy

- Molecules have discrete energy states

- A downward transition can also happen and involves the emission of a photon

Spectroscopy

- Molecules have discrete energy states

- An electromagnetic wave (a photon) induces transition between energy levels of a molecule
- The total energy of a molecule is the sum of its translation, vibration, rotation and electronic energies: $E_{tot} = E_{trans} + E_{rot} + E_{vib} + E_{elec}$
- Only E_{rot} , E_{vib} , and E_{elec} can be modified with a photon

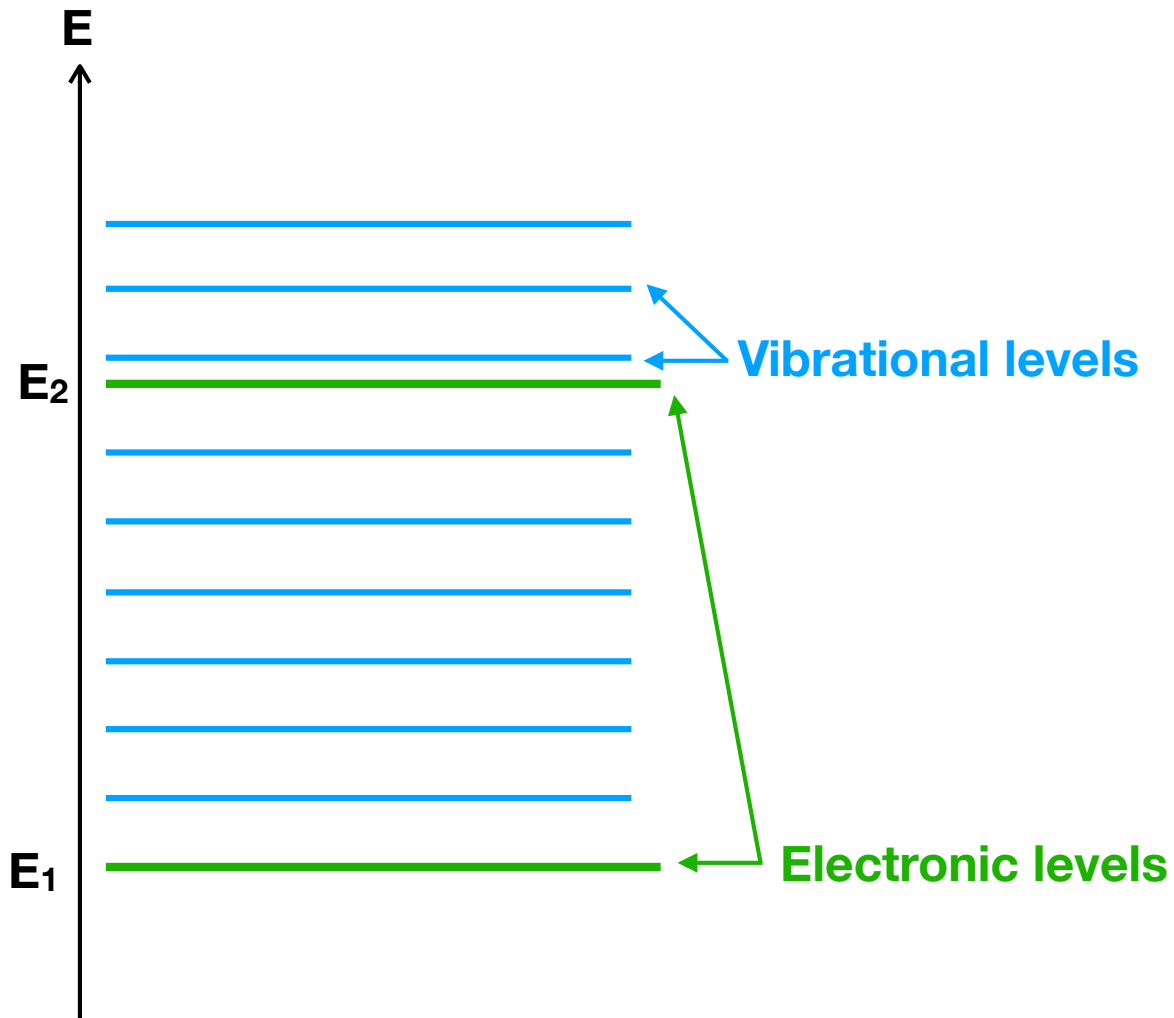

Energy levels

Transitions are induced by photons of different energies:

- V-UV ($\lambda=1-700$ nm): **electronic**
→ can break bonds in molecules (photodissociation)

Energy levels

Transitions are induced by photons of different energies:

- V-UV ($\lambda=1-700$ nm): **electronic**
→ can break bonds in molecules (photodissociation)
- IR ($\lambda=0.7-1000$ μm) : **vibrational**

Energy levels

Transitions are induced by photons of different energies:

- V-UV ($\lambda=1-700$ nm): electronic
→ can break bonds in molecules (photodissociation)
- IR ($\lambda=0.7-1000$ μm) : vibrational
- μwave ($\lambda=1-300$ mm): rotational

Structure of molecules

- Internal structure of molecules is very complex to describe because electrons behave both like particles and waves
- Classical physics is not sufficient and quantum mechanics must be used
- Impossible to know precisely where the electrons are: *Heisenberg Uncertainty Principle*
- Instead, only probabilities of finding an electron in a particular region around the atom can be calculated
- However, for simple molecules, classical physics can give correct results
- That is what will see in this course

Electronic energy levels

- For Hydrogen and hydrogen-like atoms, the Bohr model is accurate to determine the electronic energy levels:

$$E_n = -\frac{Z^2 m e^2}{8 n^2 h^2 \epsilon_0^2} = \frac{-13.6 Z^2}{n^2} \text{ eV}$$

with n : energy level

ϵ_0 : vacuum permittivity

h : Planck constant

m : atom mass

Z : nuclei charge

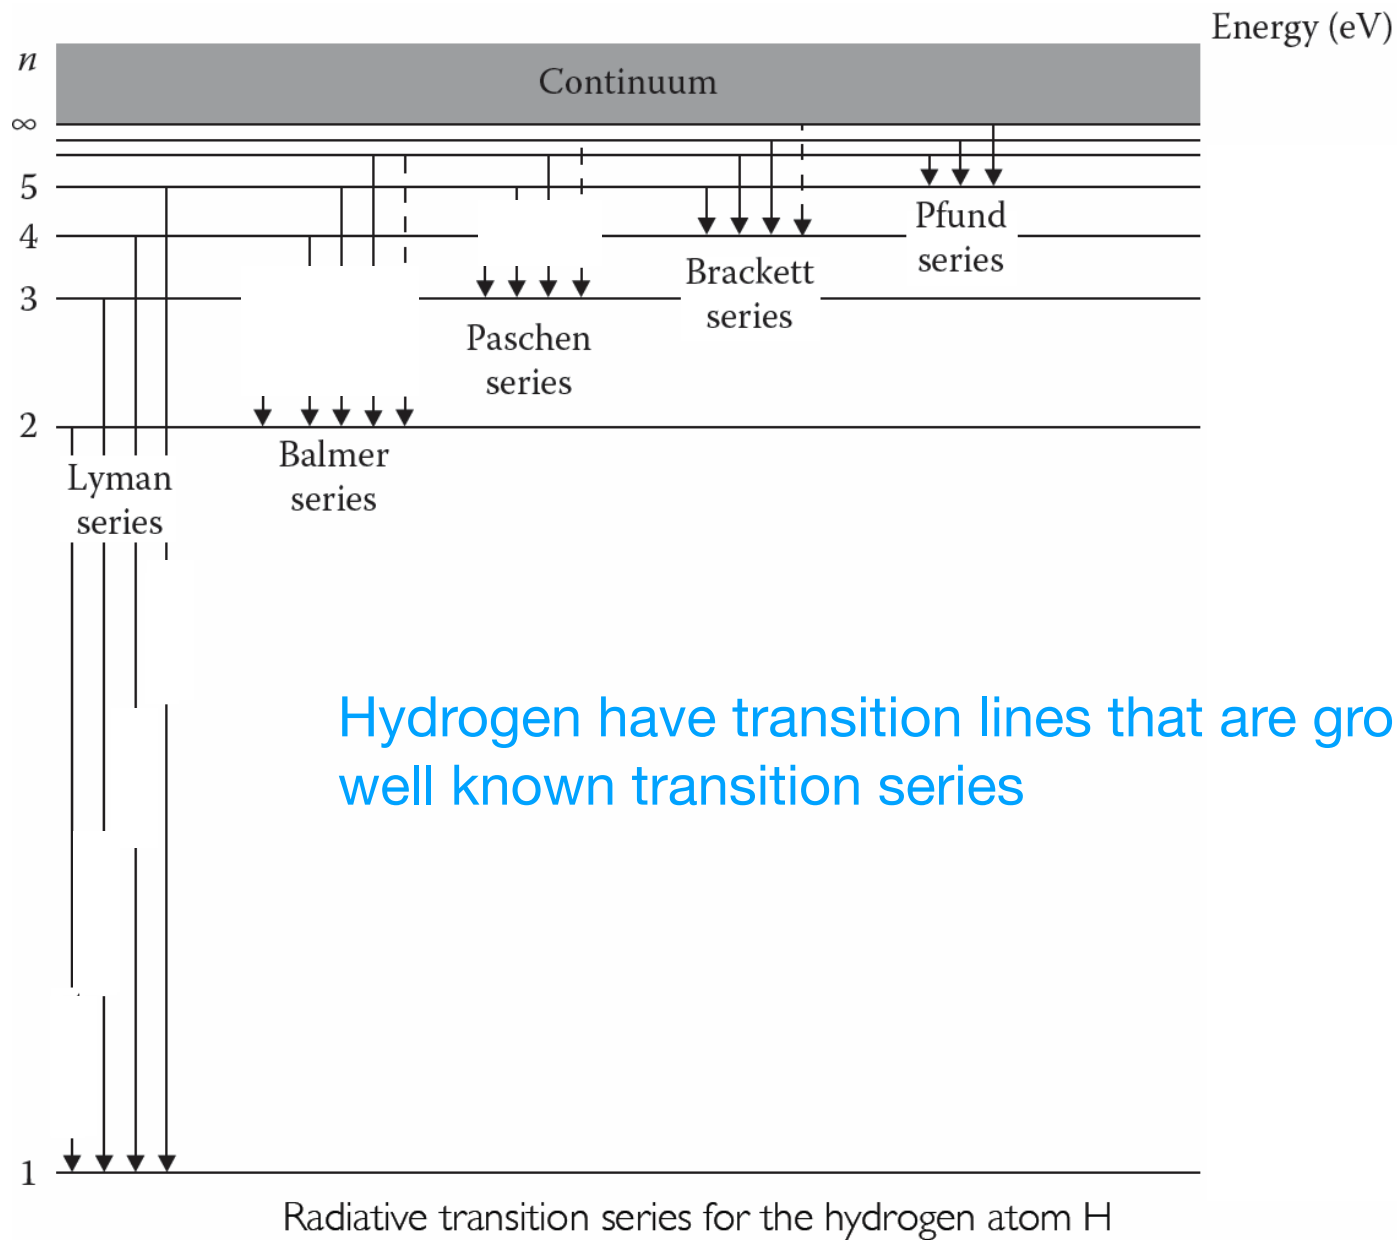

e : electron charge

- Transition between two electronic levels implies the absorption or emission of a photon with

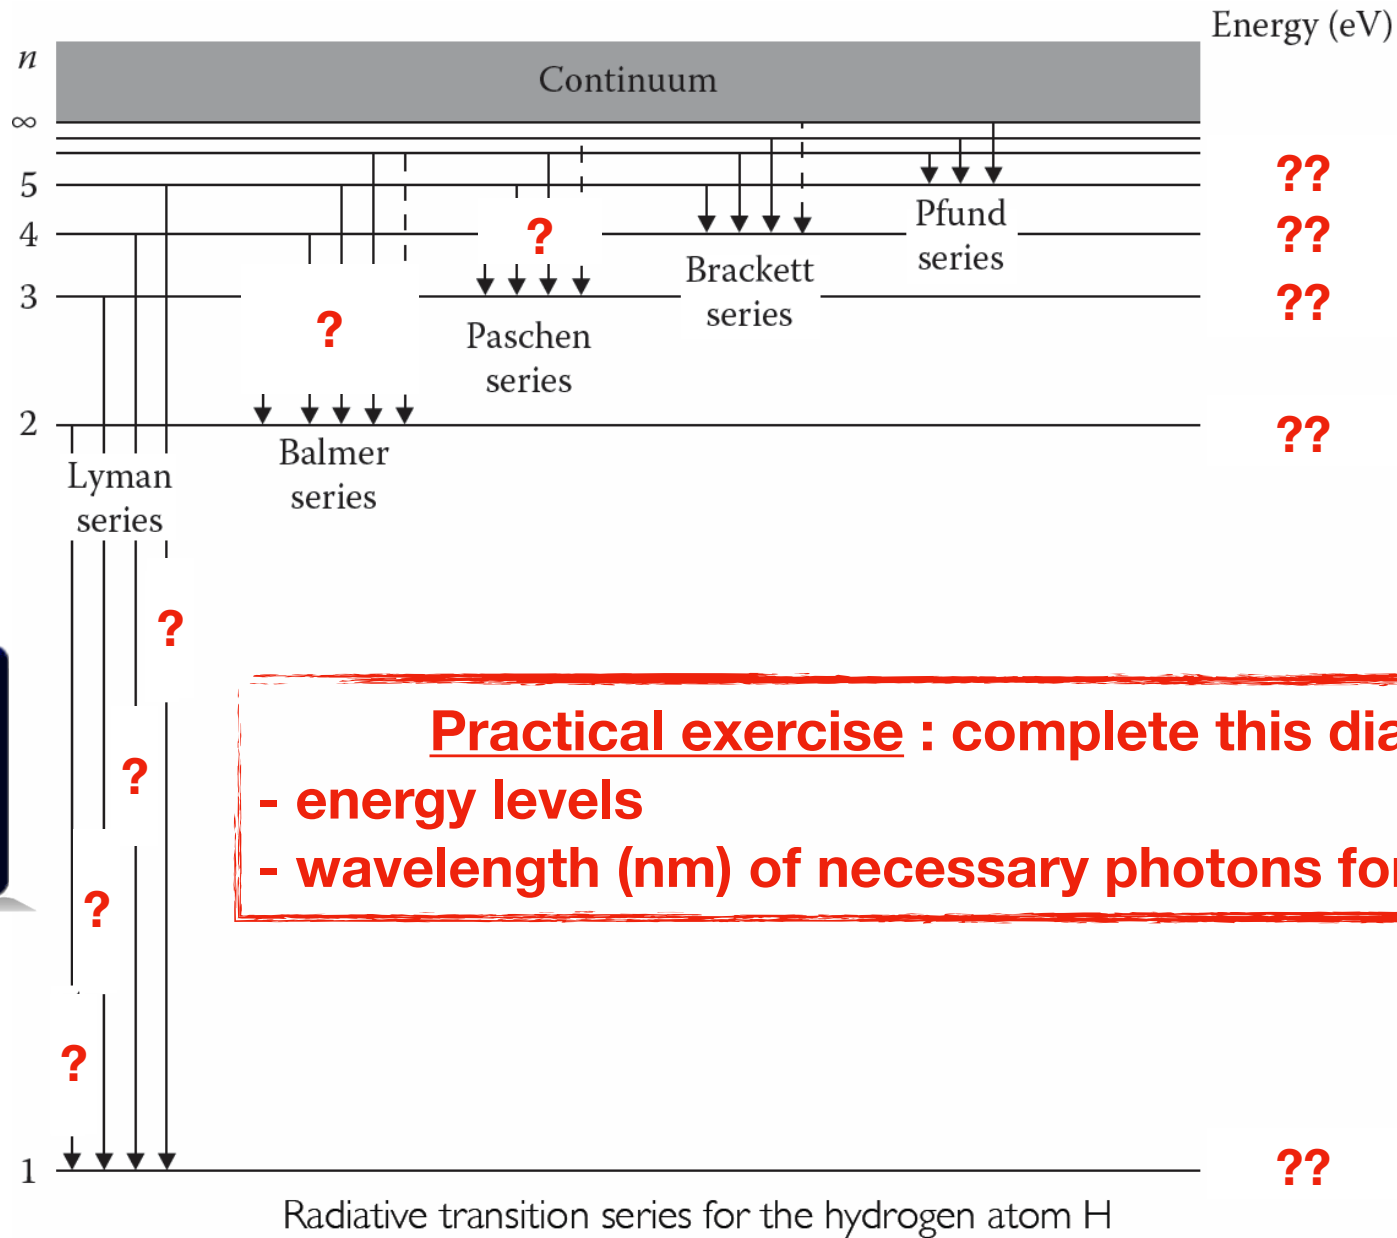

$$\Delta E = -13.6 Z^2 \left[\frac{1}{n_1^2} - \frac{1}{n_2^2} \right] \text{ eV with } n_1 > n_2$$

\Rightarrow Only photons with these energies can be absorbed or emitted

Radiative transition series for the hydrogen atom H

H α is used to observed nebula, which contain mainly hydrogen

Not as simple to calculate the energy levels of more complex molecules, but they all have discrete electronic energy levels, with specific transition lines

Vibration energy levels

- In addition to electronic levels, a molecule with several atoms has vibrational energy levels.
- Each molecule has a defined number of vibration modes and each mode has its own frequency.

H₂O

Symmetric stretch
3651.7 cm⁻¹

Symmetric bend
1595.0 cm⁻¹

Antisymmetric stretch
3755.8 cm⁻¹

CO₂

Symmetric stretch
1330 cm⁻¹

Antisymmetric stretch
2349.3 cm⁻¹

Bending
667.3 cm⁻¹

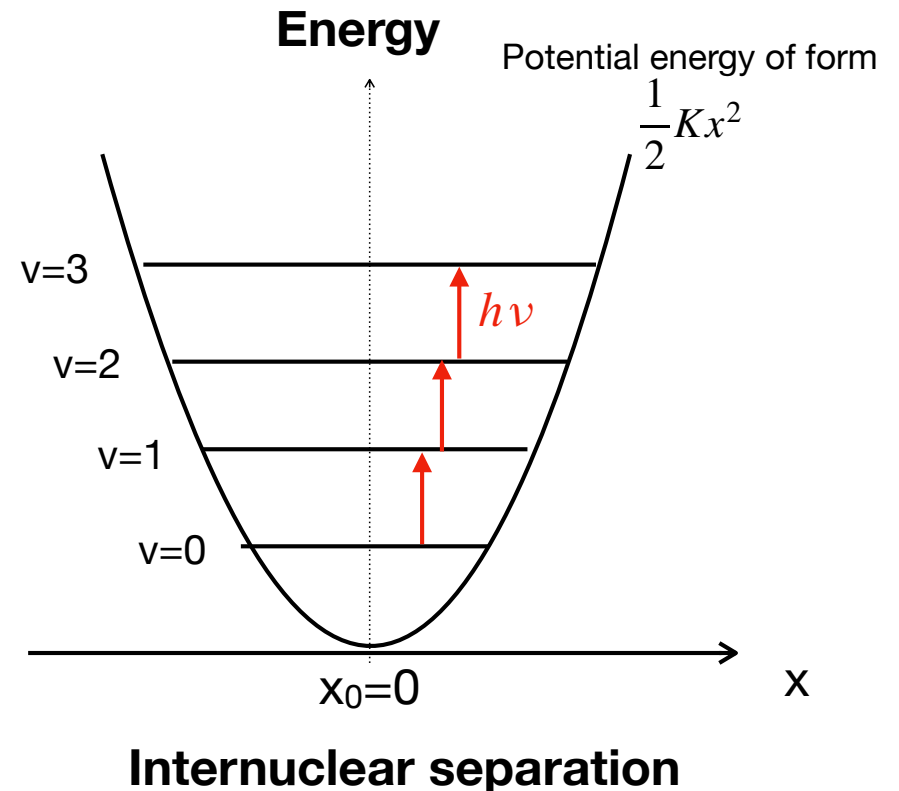

Vibration energy levels

- A diatomic molecule can be treated as a harmonic oscillator: 2 masses on a spring with a potential energy that depends upon the square of the displacement from equilibrium position: $E_p(x) = \frac{1}{2}K(x - x_0)^2$
The force constant: K

- The vibrational frequency is $\nu_{osc} = \frac{1}{2\pi} \sqrt{\frac{K}{\mu_r}}$
where the reduced mass $\mu_r = \frac{m_1 m_2}{m_1 + m_2}$

- The energy levels are $E_v = (v + \frac{1}{2})h\nu_{osc}$ with v an integer value

- Only transitions with $\Delta v = \pm 1$ are allowed by quantum mechanics.

With a finer treatment (anharmonic oscillator), we find that transitions with $\Delta v = \pm 2, \pm 3$ exist but with a low intensity

Rotation energy levels

- Finally, a diatomic molecule can rotate as a whole around an axis passing through the center of mass and perpendicular to the internuclear axis

- Treating the molecule as a rigid rotator and solving Schrödinger equation, we find that the possible energy levels are

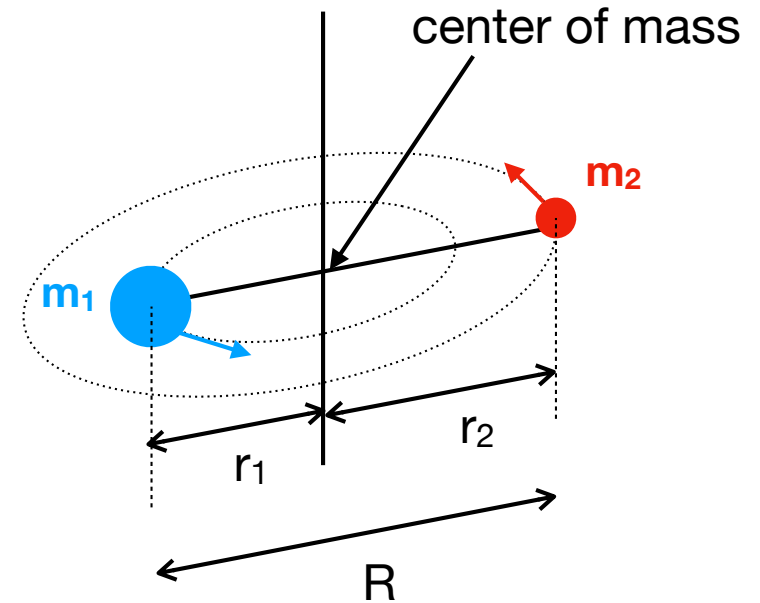

$$E_{rot} = \frac{h^2 J(J+1)}{8\pi^2 I}, \text{ with } J \text{ an integer value, the}$$

moment of inertia $I = \mu_r R^2$, and the reduced mass $\mu_r = \frac{m_1 m_2}{m_1 + m_2}$

- The rotational frequency is

$$\nu_{rot} = \frac{h}{4\pi^2} \sqrt{J(J+1)}$$

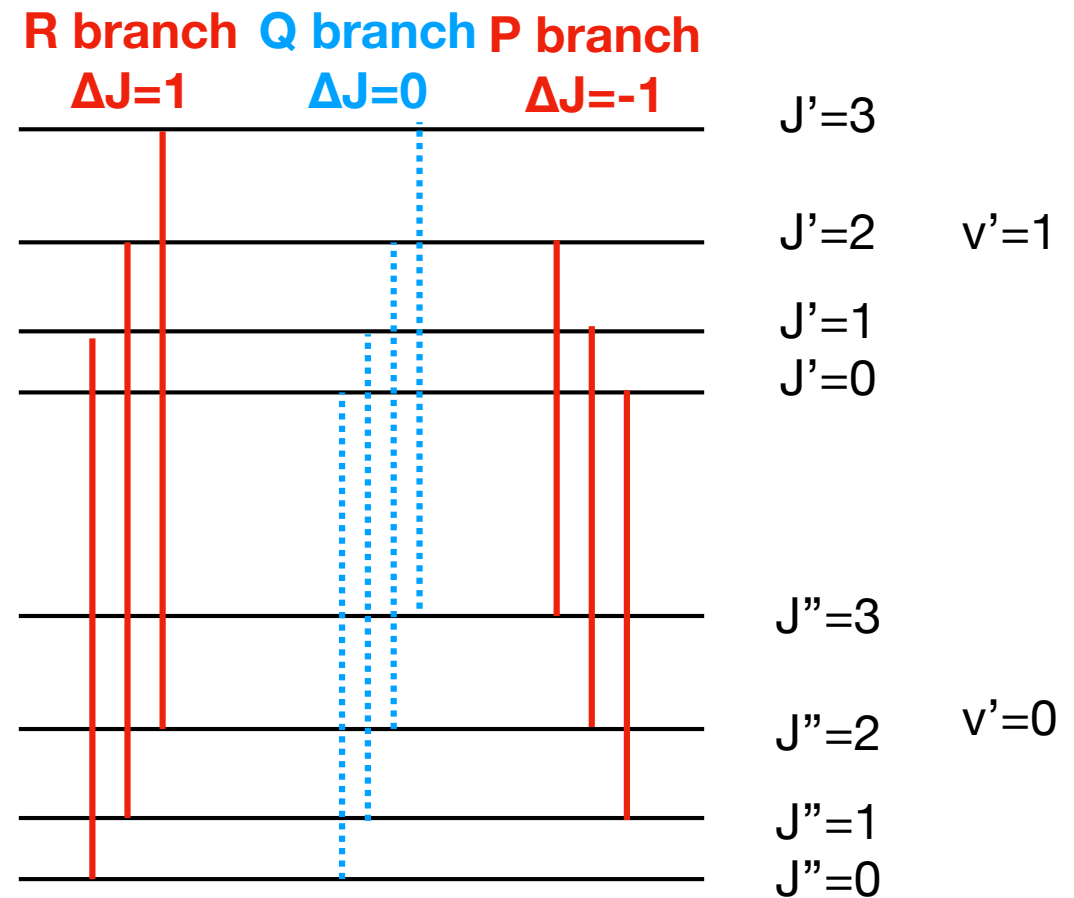

- Only transitions with $\Delta J = \pm 1$ are allowed by quantum mechanics.

To rotate, the molecule must have a dipolar moment non-null (O_2 , N_2 don't have)

Vibration-Rotation energy levels

- In reality, movements of rotation and vibration happen simultaneously.
- Rules of selection are the same $\Delta v = \pm 1$, $\Delta J = 1$ (*R branch*) and $\Delta J = -1$ (*P branch*)
- The transition with $\Delta J = 0$ is called *Q branch* but is « forbidden » (in practise, happens but with a very low probability)

Collision-Induced Absorption

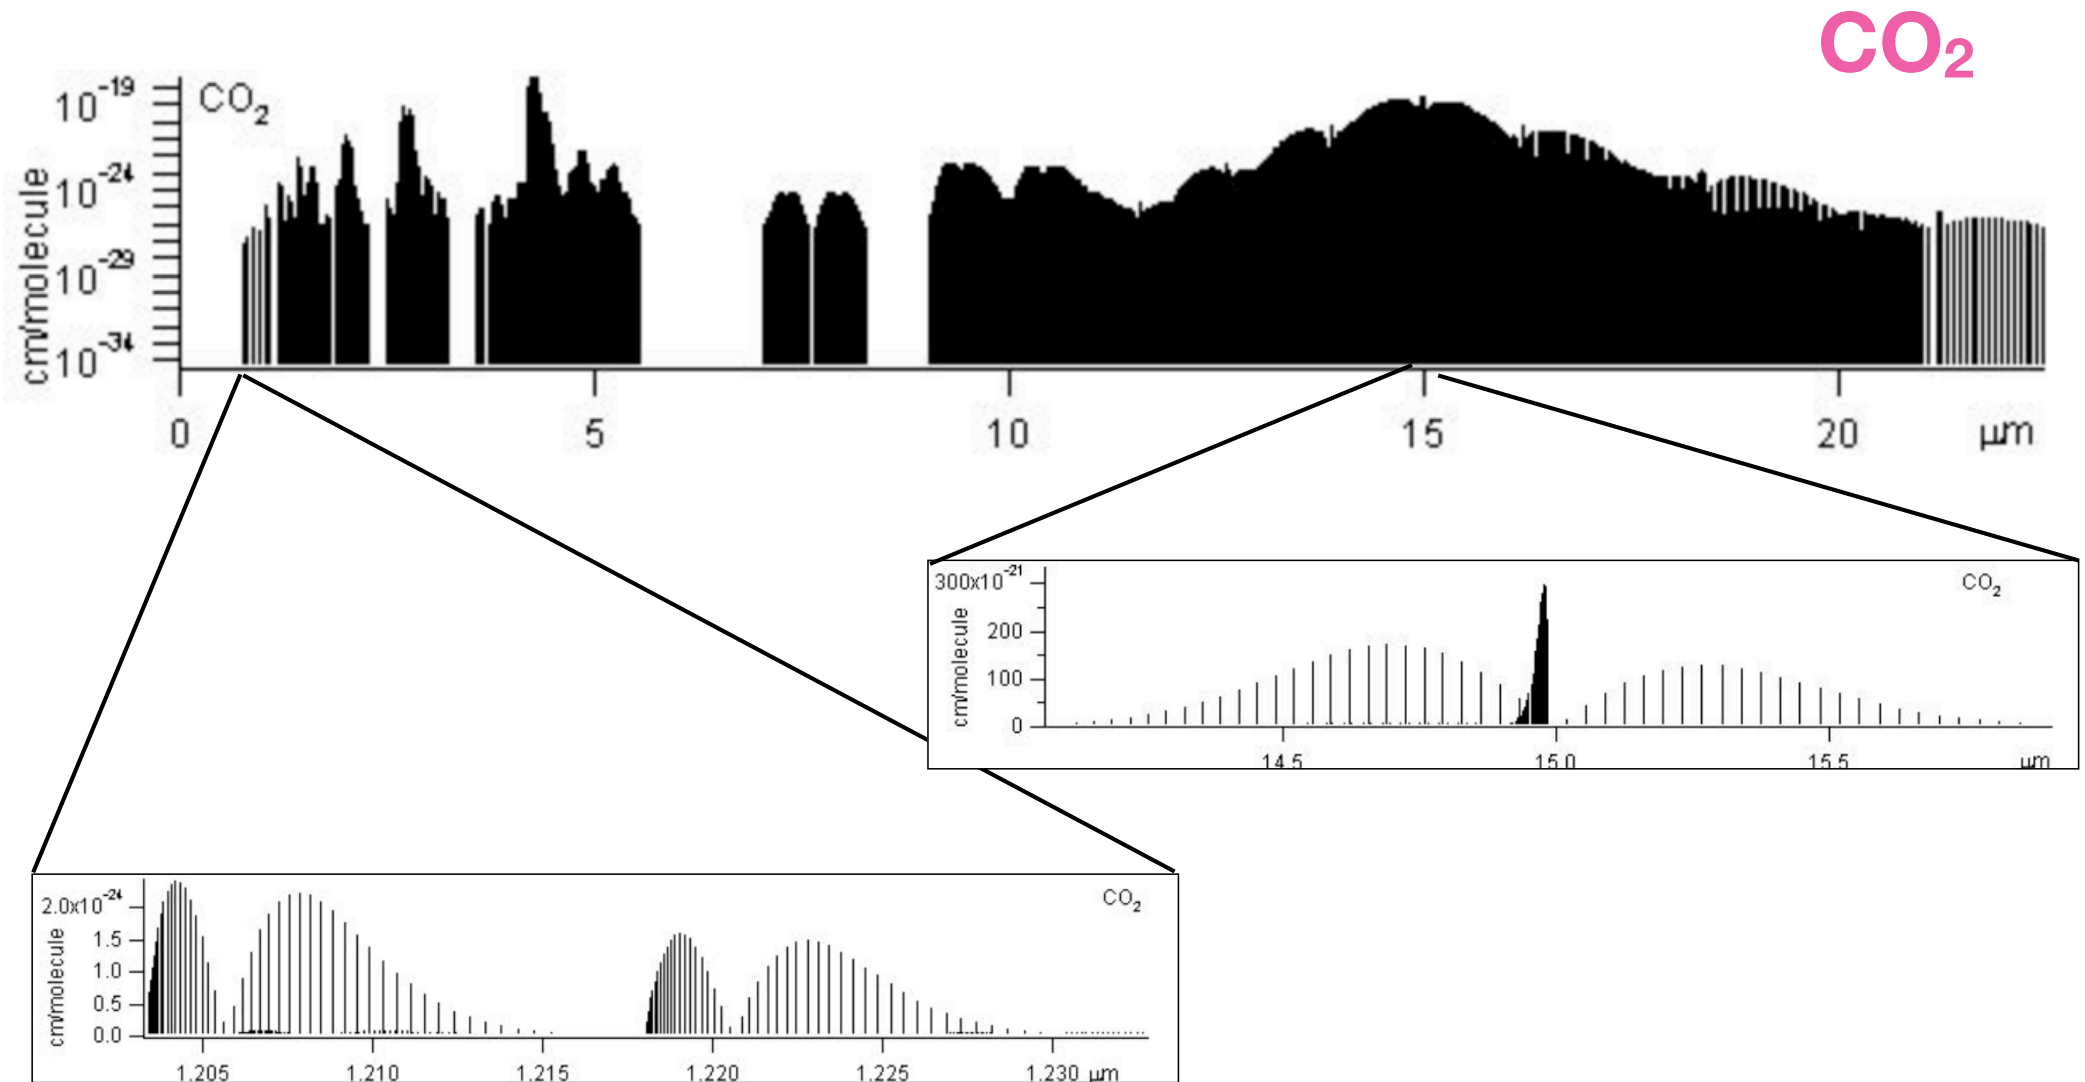

- We said previously: To rotate, the molecule must have a dipolar moment non-null, which is not the case for symmetric molecules (e.g. H_2 , O_2 , N_2 ...)
- However, if densities and/or absorption path lengths are sufficiently high, even these infrared inactive gases can absorb infrared radiation
- These molecules can thus form a « complex of interacting molecules », in which a transient dipole is created, which causes collision-induced absorption (CIA).

- CIA phenomenon plays an important role in the total absorption of radiation in atmosphere and must be considered in radiative transfer models.
- In warm exoplanets, collision-induced dipole of H_2 - H_2 and H_2 -He are the main contributors to the opacity of the atmosphere in the far-infrared.
- CIA floor is the lowest possible depth we can probe in hot Jupiter atmospheres

Molecular spectra

- Each atom or molecule has its own unique set of energy transitions, with different intensities.

Planetary Spectra

- Identification of individual molecular bands in planetary spectra permit to determine the composition of atmospheres.

Titan atmosphere Vinatier et al. 2010

- Comparison between synthetic spectra and observations
- Much better resolution for Solar System bodies than for exoplanets...

XO-1b atmosphere Tinetti et al. 2010
